

HIGHLY VENOMOUS

Mozambique Spitting Cobra

(*Naja mossambica*)

Max length
1.8 m

The Mozambique Spitting Cobra is common across its range. The diet of this snake consists largely of frogs, small mammals, birds and other snakes, including the Puff Adder. It is active on overcast days, but more active at night, often ending up in houses where people are bitten while asleep. This snake accounts for the majority of serious snakebite cases in southern Africa but fatalities are rare. It also spits its venom and does not always spread a hood when doing so. Its venom is potentially cytotoxic causing pain, swelling, blisters and in many cases severe tissue damage. Antivenom is effective against the venom of this species.
